PROJECT REPORT

Project Title: Real-Time Face and Eye Detection Using OpenCV and Haar Cascade Classifiers
Course/Domain: Computer Vision / Artificial Intelligence

Submitted By: Name: [Mayank Chaudhary]

Registration Number: 25BAI10888

Institution: Vellore Institute of Technology (VIT), Bhopal

---

1. Abstract

Computer vision is a rapidly growing field within Artificial Intelligence that enables computers to derive meaningful information from digital images and videos. This project implements a real-time object detection system capable of identifying human faces and eyes using a live webcam feed. Utilizing the OpenCV library and pre-trained Haar Cascade classifiers, the system first detects a face within the video frame. To optimize processing power and increase accuracy, the program establishes a Region of Interest (ROI) around the detected face and restricts the search for eyes exclusively to this localized area.

2. Introduction

Facial recognition and detection are fundamental components of modern biometric security, human-computer interaction, and photography. The objective of this project is to build a lightweight, efficient, and highly responsive facial feature detection program. By utilizing Haar feature-based cascade classifiers—an effective object detection method proposed by Paul Viola and Michael Jones—the system can detect faces and eyes in real-time even on machines with limited computational resources.

3. Objectives

- To capture real-time video data using a standard computer webcam.
- To process video frames by converting them into grayscale to reduce computational load.
- To successfully detect human faces in the video feed and highlight them with bounding boxes.
- To implement Region of Interest (ROI) optimization to detect eyes only within the boundaries of a detected face.

4. Technologies and Libraries Used

- **Programming Language:** Python 3.x
- **Library:** OpenCV (Open Source Computer Vision Library)
    - cv2.VideoCapture: For accessing the webcam.
    - cv2.CascadeClassifier: For loading the pre-trained AI XML files.
    - cv2.cvtColor: For color space conversion (BGR to Grayscale).
- **Algorithms:** Haar Cascade Classifiers (haarcascade_frontalface_default.xml, haarcascade_eye.xml)

5. System Architecture & Methodology

5.1 The Haar Cascade Classifier

The core of this project relies on Haar Cascades, a machine learning object detection algorithm used to identify faces in an image or a real-time video. The algorithm is trained on a lot of positive images (images of faces) and negative images (images without faces) to accurately isolate the desired features.

5.2 Step-by-Step Working Principle

1. **Initialization:** The program loads the pre-trained XML checklists for frontal faces and eyes.
2. **Video Capture:** The webcam is initialized, and a continuous loop begins to capture the video frame by frame.
3. **Preprocessing:** Each frame is captured in BGR (Blue, Green, Red) format and immediately converted to grayscale. Grayscale simplifies the algorithm's job, as it only has to process intensity (1 channel) rather than color (3 channels).
4. **Face Detection:** The detect Multiscale function scans the grayscale frame. If a face is found, a blue bounding rectangle is drawn using the coordinates (x, y, w, h).
5. **Region of Interest (ROI) Isolation:** Instead of scanning the entire frame for eyes (which could lead to false positives like identifying a round object in the background as an eye), the program crops the frame to just the face's coordinates.
6. **Eye Detection:** The system scans the newly created ROI for eyes and draws green bounding rectangles around them.

7. **Termination:** The live, annotated feed is displayed to the user until the 'q' key is pressed, safely releasing the camera resources.

6. Source Code Implementation

```python
import cv2

# 1. Load the AI checklists for BOTH faces and eyes
face_cascade = cv2.CascadeClassifier(cv2.data.haarcascades + 'haarcascade_frontalface_default.xml')
eye_cascade = cv2.CascadeClassifier(cv2.data.haarcascades + 'haarcascade_eye.xml')

# 2. Turn on your webcam
cap = cv2.VideoCapture(0)

while True:
    # 3. Read the frame and convert to black and white
    success, frame = cap.read()
    if not success:
        print("Camera not working!")
        break

    gray_frame = cv2.cvtColor(frame, cv2.COLOR_BGR2GRAY)

    # 4. Search for faces in the whole screen
    faces = face_cascade.detectMultiScale(gray_frame, scaleFactor=1.3, minNeighbors=5)

    # 5. Loop through every face found
    for (x, y, w, h) in faces:
        # Draw a blue box around the face (OpenCV uses BGR color format: Blue, Green, Red)
        cv2.rectangle(frame, (x, y), (x+w, y+h), (255, 0, 0), 2)

        # 6. Create the "Region of Interest" (ROI)
        # This acts like a digital crop of just the face area
        roi_gray = gray_frame[y:y+h, x:x+w]
        roi_color = frame[y:y+h, x:x+w]

        # 7. Search for eyes ONLY inside the cropped gray face area
        eyes = eye_cascade.detectMultiScale(roi_gray, scaleFactor=1.1, minNeighbors=10)

        # 8. Draw a green box around any eyes found inside the face
        for (ex, ey, ew, eh) in eyes:
            cv2.rectangle(roi_color, (ex, ey), (ex+ew, ey+eh), (0, 255, 0), 2)

    # 9. Show the video on screen
    cv2.imshow('Advanced AI Face & Eye Detector', frame)

    # 10. Wait for the user to press 'q' to quit
    if cv2.waitKey(1) & 0xFF == ord('q'):
        break
```

7. Results and Output

Upon execution, the system successfully activates the user's primary webcam. When a human subject enters the frame, the application instantly draws a blue rectangle around the entirety of the face. Simultaneously, smaller green rectangles accurately track the subject's eyes. The real-

time tracking remains stable even with minor head movements, and the application closes gracefully without memory leaks upon pressing the 'q' key.

(Note to student: You should take a screenshot of the program running with the boxes on your face and paste the image here before saving as a PDF!)

8. Conclusion

The project successfully demonstrates the application of computer vision for real-time biometric detection. By leveraging OpenCV and Haar Cascades, we achieved an efficient and responsive application. The use of a Region of Interest (ROI) significantly reduced the false positive rate for eye detection and minimized the computational processing required per frame, proving to be an optimal approach for real-time video analysis.

9. Future Scope

While this system is highly effective for basic detection, it can be expanded upon in the future by:

1. Upgrading to Deep Learning models (like SSD or YOLO) for better accuracy in low-light conditions.
2. Adding facial recognition logic to not only detect a face, but identify *who* the person is.
3. Implementing blink detection to ensure liveness, preventing the system from being spoofed by a printed photograph.
